Abstract

On the spouse-loving variant of the Oberwolfach Problem

Andrea Burgess
University of New Brunswick

In the 1960s, Ringel posed the Oberwolfach Problem: at a conference with \( v \) attendees, the dining room has tables of sizes \( n_1, n_2, \ldots, n_t \), where \( n_1 + n_2 + \cdots + n_t = v \). Is it possible to find a seating plan over successive nights of the conference so that each person sits next to each other person exactly once?

In graph-theoretical terms, Ringel’s problem asks for a 2-factorization of \( K_v \), in which each 2-factor is isomorphic to a given 2-factor \( F \). Such a factorization of the complete graph can exist only if \( v \) is odd. For even orders, it is common to study the maximum packing variant, in which we factor \( K_v - I \), the complete graph with the edges of a 1-factor removed; this is sometimes referred to as the spouse-avoiding variant. In this talk, we consider the minimum covering version, which we nickname the spouse-loving variant. Here, given a 2-factor \( F \) of even order \( v \), we seek an \( F \)-factorization of \( K_v + I \), the complete graph with the edges of a 1-factor duplicated. We discuss the problem in the cases that the 2-factor \( F \) is uniform or bipartite.

This talk includes joint work with Noah Bolohan, Iona Buchanan, Mateja Sajna and Ryan Van Snick.
