Quasigroups and Latin squares.

Ruth Moufang (1935)

A **quasigroup of order** n is a pair (Q, \cdot) formed by

- a finite set Q of n elements
- a product \cdot endowed of left and right division.

Its multiplication table is a **Latin square**.

$S_n \equiv$ Symmetric group on $\{1, \dots, n\}$.

Isotopism: $\Theta = (f, g, h) \in S_n^3$

Row-permutation (f), column-permutation (g), symbol-permutation (h).

- $f = g = h \Rightarrow$ Isomorphism.
- $f = g \Rightarrow$ Strong isotopism.

$$L \equiv \begin{array}{|c|c|c|} \hline 1 & 2 & 3 \\ \hline 2 & 3 & 1 \\ \hline 3 & 1 & 2 \\ \hline \end{array} \Rightarrow L^\Theta \equiv \begin{array}{|c|c|c|} \hline 2 & 3 & 1 \\ \hline 3 & 1 & 2 \\ \hline 1 & 2 & 3 \\ \hline \end{array}$$
$$\Theta = ((1\ 2)(3), (1\ 2)(3), (2\ 3)(1)) \in S_3^3$$

Latin squares as scramblers in Cryptography.

[V. Dimitrova V., S. Markovski, 2007] *Classification of quasigroups by image patterns.* Proc. 5th CIIT, 152–160.

Vesna Dimitrova

Smile Markovski

- A quasigroup (Q, \cdot)
- A plaintext $T = t_1 \dots t_m$, with $t_i \in Q$
- A leader symbol $s \in Q$

Encryption: $E_s(T) = e_1 \dots e_m$

$$e_i := \begin{cases} s \cdot t_1, & \text{if } i = 1, \\ e_{i-1} \cdot t_i, & \text{otherwise.} \end{cases}$$

$$\left\{ \begin{array}{l} Q \equiv \begin{array}{|c|c|c|} \hline 1 & 2 & 3 \\ \hline 2 & 3 & 1 \\ \hline 3 & 1 & 2 \\ \hline \end{array} \\ T = 122333122333 \end{array} \right. \Rightarrow \begin{cases} E_1(T) = 123213312132 \\ E_2(T) = 231321123213 \\ E_3(T) = 312132231321 \end{cases}$$

Open problem: A comprehensive analysis of their fractal dimensions.

Image patterns arising from Latin squares.

There is an interesting relation with Latin square isomorphisms:

Lemma (F., Álvarez, Gudiel, 2019)

- *Two isomorphic Latin squares L_1 and L_2 by means of isomorphism f*
- *A plaintext T*
- *A tuple of leader symbols S*

Then, $\mathcal{P}_{S,T}(L_1)$ and $\mathcal{P}_{f(S),f(T)}(L_2)$ coincide up to permutation f of their symbols.

Main question: Can we use image patterns for distinguishing non-isomorphic Latin squares?

CONTENTS

Can we find an efficient method for distinguishing standard sets?

CONTENTS

- 1 Preliminaries.
- 2 Standard sets of image patterns.
- 3 The mean fractal dimension.

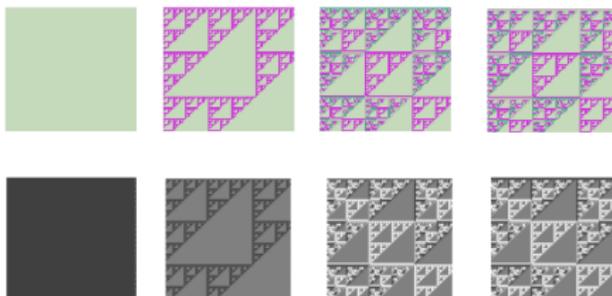

Homogenized standard sets.

$\mathfrak{P}_n = \{c_1, \dots, c_n\} \equiv$ Grayscale palette such that $\text{Intensity}(c_i) = \frac{i}{n}$.

A standard set of image patterns of a Latin square of order n is said to be **homogenized** if the colors of \mathfrak{P}_n appear in natural order (according to their intensity) when the image pixels are read row by row then column by column.

$\mathcal{H}_{r,m}(L) \equiv$ Set of homogenized standard sets of $L \in \text{LS}_n$.

3	1	4	2
4	3	2	1
2	4	1	3

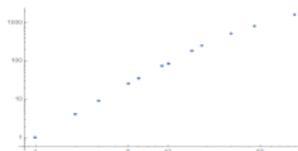

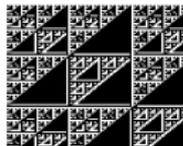

Differential box-counting fractal dimension.

- $L \in \text{LS}_n$. $\text{Div}(r, m) \equiv$ Common divisors of r and m .
- $I_{i,j,k}(\mathcal{P}_{r,m;s}(L)) \equiv$ Range of gray-level intensities in the (i,j) -cell of the $\frac{r}{k} \times \frac{m}{k}$ grid of $\mathcal{P}_{r,m;s}(L)$, with $k \in \text{Div}(r, m)$.

$$I_k(\mathcal{P}_{r,m;s}(L)) := \sum_{(i,j) \in \left[\frac{r}{k}\right] \times \left[\frac{m}{k}\right]} (1 + I_{i,j,k}(\mathcal{P}_{r,m;s}(L))).$$

Based on the *differential box-counting method*, we define the **differential box-counting fractal dimension** $D_B(\mathcal{P}_{r,m;s}(L))$ of $\mathcal{P}_{r,m;s}(L)$ as the slope of the linear regression line of the set of points

$$\{(\log(I_k(\mathcal{P}_{r,m;s}(L))), \log(1/k)) : k \in \text{Div}(r, m)\}.$$

Mean fractal dimension.

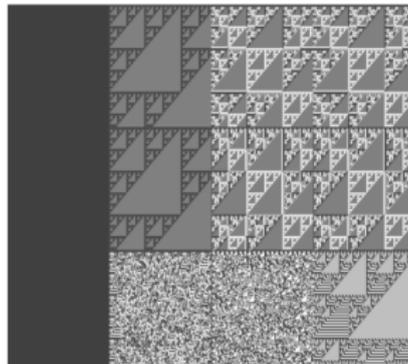

The mean value of the n differential box-counting fractal dimensions, averaged over $\text{Div}(r, m)$, is the **mean fractal dimension** $D_B(\mathcal{H}_{r,m}(L))$.

Theorem

- $L_1, L_2 \in \text{LS}_n$.

If L_1 and L_2 are isomorphic, then $D_B(\mathcal{H}_{r,m}(L_1)) = D_B(\mathcal{H}_{r,m}(L_2))$.
